Predictive Modeling of Airbnb Stock Prices Using Multiple Regression Analysis

Mannan Anand

ABSTRACT

In the aftermath of the COVID-19 pandemic, the travel industry has seen unprecedented volatility, making it a focal point for investors seeking to capitalize on market recoveries.

Airbnb, a leading player in this sector, represents a unique investment opportunity due to its innovative business model and significant market share in alternative lodging. This study endeavors to develop a predictive model for Airbnb's daily stock prices, utilizing data from other Consumer Discretionary stocks listed on the S&P 500 index. The volatility experienced by the travel industry, particularly during the market fluctuations post-COVID-19, provides a compelling backdrop for this analysis. Airbnb's resilience and adaptability during the pandemic, coupled with its ability to bounce back as travel restrictions eased, highlight its potential for growth. By leveraging historical stock price data and employing multiple regression techniques, this analysis aims to identify key predictors among S&P 500 constituents that influence Airbnb's stock performance.

This analysis identifies key significant predictors such as eBay, Caesar's Entertainment,

Darden Restaurants, and Starbucks, evidenced by 65.33% explanation of the dataset's

variability without any multicollinearity issues to equip investors with a strategic tool for

predicting Airbnb's stock movements, enhancing decision-making for both short-term

trading and long-term investments.

DATA

The predictive analysis of Airbnb's stock prices is underpinned by a robust dataset extracted from the Consumer Discretionary sector of the S&P 500 index. The dataset encompasses daily stock prices over the period from April 1, 2023, to March 31, 2024, providing a comprehensive view of market dynamics during this timeframe. This period is particularly significant as it captures the ongoing market adjustments post-COVID-19, a critical factor for companies in the travel industry, including Airbnb.

The dataset includes a total of 249 observations, each representing a trading day's closing stock prices for Airbnb and selected companies that potentially influence or share market behaviors with Airbnb. These companies include Home Depot (HD), Tesla (TSLA), eBay (EBAY), Deckers Outdoor Corporation (DECK), and several others, reflecting a mix of direct and indirect market influences.

Rationale for Variable Selection:

- Dependent Variable: Airbnb (ABNB) was selected as the dependent variable to
 focus the predictive analysis on its stock price movements, which are of primary
 interest to stakeholders and investors.
- Independent Variables: Variables like HD, TSLA, and EBAY were chosen based on their potential influence on Airbnb's stock price through consumer spending patterns, technological advancements, and e-commerce trends, respectively.
 These factors are presumed to have significant impacts on Airbnb's performance, especially in the rapidly changing landscape of the travel and accommodation industry.

METHODOLOGY

The analysis followed several structured steps to ensure rigor and accuracy:

1. Exploratory Data Analysis (EDA):

- Distribution and Relationship Visualization: Using PROC SGPLOT and PROC UNIVARIATE, the distribution of stock prices and the relationships between the variables were visualized. This helped identify the central tendencies, variability, and potential outliers in the data.
- Summary Statistics: PROC MEANS provided detailed descriptive statistics for each variable, offering insights into the data's structure and underlying trends.

2. Correlation Analysis:

 Determining Relationships: PROC CORR was employed to assess the strength and direction of linear relationships between Airbnb's stock prices and the independent variables. This step was crucial to narrowing down the list of potential predictors based on their correlation coefficients.

3. Regression Analysis:

Using PROC REG, a stepwise regression approach was adopted to
iteratively select the most statistically significant predictors for the model.
This method facilitated the inclusion and exclusion of variables based on
their p-values and overall contribution to the model's explanatory power.

 Model Refinement: Interaction terms and quadratic terms were tested within the regression framework to explore complex relationships and nonlinear effects that could enhance the model's predictive accuracy.

4. Model Evaluation and Selection:

- Criteria for Model Comparison: Different models were compared using
 Adjusted R², Cp, and PRESS statistics to determine the best fit. Each statistic
 provided a different lens through which the model's effectiveness could be
 assessed, ensuring a comprehensive evaluation.
- Diagnostic Checking: The analysis of residuals and fit plots via PROC REG
 verified the assumptions of normality, homoscedasticity, and the absence of
 multicollinearity among the predictors.

RESULTS

Exploratory Data Analysis (EDA): The initial phase involved a detailed examination of the stock prices of Airbnb and selected S&P 500 companies within the Consumer Discretionary sector. The primary outcomes from the EDA include:

- Mean: The average price of ABNB is 133.77, indicating the central tendency over the observed period.
- Volatility: A standard deviation of 15.33 suggests moderate fluctuations.
- Range and IQR: The range (104.42 to 168.18) and IQR (22.55) show substantial
 variability, indicating periods of significant price change, which are important for
 modeling volatility.

Comparative Analysis of Other Stocks

Potential Good Predictors

ETSY shows a standard deviation of 12.494, skewness of 0.460, and kurtosis of 0.930, indicating moderate volatility and a distribution shape not too dissimilar from

 ABNB. Stocks like MCD with lower volatility (std dev of 12.318) but not too far off
 from ABNB could provide a stable yet related dynamic to ABNB's price movements.

Poor Predictors

Highly Volatile Stocks: Extremely volatile stocks might distort the prediction model
for a relatively less volatile stock like ABNB. For example, AZO with a high standard
deviation of 189.339 and extreme values in price could introduce noise rather than
predictive power. Stocks like TSLA or AZO are likely to behave differently under
market conditions compared to ABNB.

CORRELATION ANALYSIS

The correlation analysis helped narrow down the list of potential predictors by highlighting stocks that showed significant linear relationships with Airbnb's stock prices. Stocks like Amazon (AMZN) and surprisingly Tesla (TSLA) demonstrated strong positive correlations, making them prime candidates for the regression model.

High Correlation:

Stocks like Amazon (AMZN), Booking Holdings (BKNG), and Chipotle Mexican Grill (CMG) show high correlations with ABNB (e.g., AMZN at 0.83045, BKNG at 0.79076, CMG at 0.72334). These stocks, due to their strong correlations, are likely good predictors and should be retained for further analysis.

Low or Negative Correlation:

Some stocks exhibit very low or even negative correlations with ABNB, which might make them less useful for predicting ABNB's prices. For instance, Ford Motor Company (F) shows a correlation of 0.22206, which is relatively low, suggesting it has little predictive power regarding ABNB's price movements. BorgWarner (BWA) has a negative correlation (-0.40140) with ABNB, indicating a divergent movement pattern which might not be useful for the prediction model.

StepWise Regression:

In our analysis, we employed stepwise regression to determine the optimal combination of independent variables for predicting Airbnb stock prices. Variables were iteratively added and removed based on their p-values and the overall fit of the model. This approach refined the model by retaining only those variables that significantly contributed to predicting Airbnb's stock price. This method allows us to systematically explore the potential predictors among a larger set of variables, ultimately leading to a parsimonious model with strong predictive performance.

Stepwise Regression Analysis Summary Table

Step	Variable Entered	Variable Removed	Model R- Square	C(p)	F Value	Pr>F
1	HD	Kemoved	0.7933	524.682	947.69	<.0001
2	TSLA		0.8335	376.834	59.47	<.0001
3	EBAY		0.8631	268.835	52.86	<.0001
4	DECK		0.8848	189.958	46.00	<.0001
5	CMG		0.8969	146.892	28.53	<.0001
6	HAS		0.9044	120.888	19.04	<.0001
7	CZR		0.9085	107.768	10.69	0.0012
8	DRI		0.9167	79.2161	23.64	<.0001
9		CMG	0.9160	79.5811	1.83	0.1774
10		HAS	0.9148	82.0840	3.47	0.0636
11	RL		0.9198	65.7273	14.81	<.0001
12	SBUX		0.9213	61.9128	4.76	0.0300
13		HD	0.9204	63.2440	2.73	0.0998
14	LOW		0.9221	58.8790	5.27	0.0226
15	AMZN		0.9243	52.6691	6.97	0.0089

Model Selection Criteria (R², Adjusted R², Cp, PRESS):

- Adjusted R-Square and Cp Analysis: These methods were employed to evaluate the goodness-of-fit of the models. Models with the highest adjusted R² values and lowest Cp values were considered better. This analysis led to further refinement by focusing on a subset of variables that maximized explanatory power while minimizing redundancy and multicollinearity.
- PRESS Statistic: This criterion was used to assess the predictive power of the model. The PRESS results influenced the final selection of variables, prioritizing those that enhance predictive accuracy on unseen data.

Based on that, for further testing using R², Adjusted R², Cp, and PRESS criteria, the best model to choose would be **Model 15** because:

Step	Model Variables	Model R- Square	C(p)	F Value	Pr > F
15	AMZN, EBAY, CZR, DECK, DRI, LOW, RL, SBUX, TSLA	0.9243	52.6691	324.43	<.0001

- R-Square: This model has the highest R-Square value of 0.9243, indicating that it
 explains about 92.43% of the variability in Airbnb's stock prices, which is the highest
 among all steps.
- **C(p) Value**: The C(p) value for this model is the lowest among all models at 52.6691, suggesting a good balance of model complexity and predictive power.
- Significance: All variables in this model are significant at the 0.0500 level as indicated by their Pr > F values, making it a robust choice for detailed evaluation.

Based on these criteria, the best models seems to be the model with 9 variables:

• Adjusted R-Square: 0.9215

• **R-Square**: 0.9243

• **C(p)**: 10.000

• Variables in the Model: AMZN, EBAY, CZR, DECK, DRI, LOW, RL, SBUX, TSLA

However, per PRESS statistic, the best model is the one that includes the variables: EBAY,

CZR, DECK, DRI, LOW, RL, SBUX, TSLA. At step 10, the PRESS value is 4862.3340, which is

the lowest PRESS value in the stepwise selection process, indicating this model has the

best predictive performance out of all the models considered. Let's evaluate it further to

test its utility:

Model Statistics:

• R-Square: 0.9221 indicates that approximately 92.21% of the variance in ABNB is

explained by the model.

• Adjusted R-Square: 0.9195 adjusts the R-Square for the number of predictors, still

suggesting a strong model fit.

• F Test:

 H_0 : All coefficients = 0

Ha: Atleast one coefficient is not equal to zero

With an F Value of 355.28 and P value < 0.001 we reject the null hypothesis that this model

is not statistically significant. Therefore, this model is of utility.

Now, to further refine this model and check for multicollinearity, we can calculate the Variance Inflation Factor (VIF) for each predictor variable. VIF quantifies how much the variance is inflated due to multicollinearity in the model. Generally, a VIF above 10 indicates high correlation and a problematic amount of collinearity.

After running a **PROC REG**, we obtain more details for our model:

Parameter Estimates								
Variable	Label	DF	Parameter Estimate	Standard Error	t Value	Pr > t	Variance Inflation	
Intercept	Intercept	1	12.30406	10.13480	1.21	0.2259	C	
EBAY	EBAY	1	0.90468	0.18109	5.00	<.0001	3.60286	
CZR	CZR	1	1.15882	0.13782	8.41	<.0001	5.60622	
DECK	DECK	1	0.07103	0.00654	10.86	<.0001	11.83621	
DRI	DRI	1	-0.38767	0.04990	-7.77	<.0001	2.81470	
LOW	LOW	1	0.13141	0.05724	2.30	0.0226	10.20232	
RL	RL	1	0.18435	0.04528	4.07	<.0001	14.59776	
SBUX	SBUX	1	-0.20324	0.08062	-2.52	0.0124	2.44964	
TSLA	TSLA	1	0.05729	0.01345	4.26	<.0001	2.98406	

Hypothesis for t-tests:

- Null Hypothesis (H0): There is no relationship between the predictor variable and the dependent variable (the coefficient is zero).
- Alternative Hypothesis (H1): There is a relationship between the predictor variable and the dependent variable (the coefficient is not zero).

Given that all variables except the Intercept have p-values significantly less than 0.05, we reject the null hypothesis for these predictors and conclude that they have a significant relationship with Airbnb's stock price.

However, DECK, LOW and RL have unreliably high VIFs (>10), so we will be removing them from our model, reducing multicollinearity significantly, but at the expense of reduced R² (0.6533) and Adj. R² (0.6462), but a very good coefficient of variation (6.81):

				Analysis of Variance								
	Source		D		Sum of quares		Mea Squa		Val	ue	Pr > F

Now, we will be testing potential interaction or second order models to see if they add any statistical significance to our model:

Model Description	Variables Included	Rationale
Main Effects Model	EBAY, CZR, DRI, SBUX, TSLA	All variables are statistically significant predictors with low VIFs, indicating minimal multicollinearity.
Model with Interaction Terms	Main effects + All pairwise interactions	Interactions will help identify if the effect of one predictor on the dependent variable changes with the level of another predictor.
Model with Quadratic Terms	Main effects + Quadratic terms for each variable	Quadratic terms will allow us to capture non- linear relationships between the predictors and the dependent variable.

Including these terms leads to excessively high Variance Inflation Factors (VIFs). VIF values well above the acceptable threshold indicate severe multicollinearity issues, which compromise the interpretability and predictive reliability of the model.

For our regression analysis, models containing both interaction and quadratic terms, are significant:

wode	With	Interaction	on term	S
		REG Procedu del: MODEL1	10000	
Test 1 Res	ults fo	r Dependent	Variable A	BNB
Source	DF	Mean Square	F Value	Pr > F
Numerator	9	845.01768	15.71	<.0001
Denominator	234	53.80331		

There is a clear interaction in EBAY and CZY (slice-plot), and the whole interaction model is significant

mous		n Quadrat					
		REG Procedu del: MODEL	2.30 %				
Test 1 Results for Dependent Variable ABNB							
Source	DF	Mean Square	F Value	Pr > F			
Numerator	5	943.87745	14.52	<.0001			
Denominator	238	65.02414					

Quadratic Model is Also Significant

Null Hypothesis (H0): All terms are jointly zero, implying no significant effects on Airbnb's stock price.

Alternative Hypothesis (Ha): At least one term is not zero, indicating a significant effect on Airbnb's stock price.

Given that the p-value is less than .0001, we reject the null hypothesis. This suggests that at least one of the interaction terms and quadratic terms significantly affects Airbnb's stock price, thus contributing to the predictive power of the model. However, every single variable (both interaction and quadratic) yielded VIFs ranging from a few 100s to 1000s. Such high VIFs signal that the predictor variables are explaining the same variance within the model, creating redundancy, and diminishing the model's performance. While these terms can sometimes capture complex relationships within the data, their inclusion has rendered our model unstable and unreliable for predictive purposes.

Hence, we conclude that the interaction and quadratic models are unsuitable for our current analysis of Airbnb stock prices. Instead, we will proceed with the main effects model that maintains low VIFs and ensures a more parsimonious and interpretable model.

For 249 observations in the dataset, our main effects model possesses the following:

- R-Square (R²): 0.6533, indicating that approximately 65.33% of the variability in
 Airbnb's stock price can be explained by the model's predictors.
- **Adjusted R-Square**: 0.6462, which adjusts the R² for the number of predictors in the model, suggesting a strong fit with consideration for the number of variables.
- Root Mean Square Error (Root MSE): 9.11633, a measure of the average deviation of the predictions from the actual values.

 F Value: 91.59, which is highly significant (Pr > F < .0001) indicating the model is statistically significant and the predictors explain a significant amount of the variance in Airbnb's stock prices compared to the model with no predictors.

Parameter Estimates:

- Intercept: 121.48383, suggesting the baseline value of ABNB when all other variables are zero.
- **EBAY**: Coefficient = 1.23638, p-value < .0001. Each unit increase in EBAY is associated with a 1.23638 unit increase in ABNB, holding all else constant.
- **CZR**: Coefficient = 0.71700, p-value = 0.0005. Each unit increase in CZR is associated with a 0.71700 unit increase in ABNB, holding all else constant.
- DRI: Coefficient = 0.58569, p-value < .0001. Each unit increase in DRI is associated
 with a 0.58569 unit increase in ABNB, holding all else constant.
- **SBUX**: Coefficient = -1.60867, p-value < .0001. Each unit increase in SBUX is associated with a 1.60867 unit decrease in ABNB, holding all else constant.
- **TSLA**: Coefficient = -0.04627, p-value = 0.0868. TSLA is not statistically significant at the 0.05 level, but it is at the 0.1 level, indicating a weaker association with ABNB.

Variance Inflation Factor (VIF):

All VIF values are below 5, which indicates that there is no concerning
multicollinearity within the model. This ensures that our model's coefficients are
reliable and not unduly influenced by redundant information across the predictors.

Predictive Equation:

The final equation for predicting Airbnb's stock price (ABNB) based on this model is:

ABNB =
$$121.484 + 1.236 \times (EBAY) + 0.717 \times (CZR) + 0.586 \times (DRI)$$

 $-1.609 \times (SBUX) - 0.046 \times (TSLA)$

This equation allows us to input values for the EBAY, CZR, DRI, SBUX, and TSLA variables to predict the ABNB stock price. Given the low VIFs, the significant overall model, and the strong R-squared value, this model is deemed free from multicollinearity issues and capable of providing reliable predictions.

CONCLUSION

The analysis concluded with a regression model predicting Airbnb's stock price with variables EBAY, CZR, DRI, and SBUX, which demonstrated a good fit with an R-squared of 0.6533. The model avoided multicollinearity, confirmed by low VIF scores. However, the inclusion of the TSLA variable, despite its higher p-value, was a limitation due to its marginal significance.

For further research, adding a qualitative variable such as the GICS Sub-Industry could differentiate the impact of various sectors on Airbnb's stock price. Repeating this analysis with more data, like macroeconomic factors or at different time frequencies, could also yield more nuanced insights. The future incorporation of such variables could refine the model's predictive capability and enhance its usefulness for strategic decision-making.
